Assignment 2

Computer Networks (CS 456)

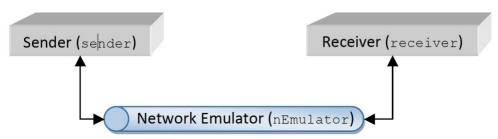

A congestion-controlled Go-Back-N Protocol

Due Date: Monday March 22 2021, at midnight (11:59 PM)

Work on this assignment is to be completed individually

Assignment Objective

The goal of this assignment is to implement a **congestion-controlled Go-Back-N** protocol, which could be used to transfer a text file from one host to another across an unreliable network. The protocol should be able to handle network errors (packet loss), packet reordering, and duplicate packets. For simplicity, your protocol is unidirectional, i.e., data will flow in one direction (from the sender to the receiver) and the acknowledgements (ACKs) in the opposite direction. To implement this protocol, you will write two programs: a sender and a receiver, with the specifications given below. To test your implementation, you will write a third a third program that will emulate an unreliable network link.

When the sender needs to send packets to the receiver, it sends them to the network emulator instead of sending them directly to the receiver. The network emulator then forwards the received packets to the receiver. However, it may randomly discard received packets. The same scenario happens when the receiver sends ACKs to the sender.

Packet Format

All packets exchanged between the sender and the receiver should have the following structure:

The type field indicates the type of the packet. It is set to 0 if it is an ACK, 1 if it is a data packet, 2 if it is an end-of-transmission (EOT) packet (see the definition and use of an end-of-transmission packet below). For data packets, seqnum is the modulo 32 sequence number of the packet. The sequence number of the first packet should be zero. For ACK packets, seqnum is the sequence number of the packet being acknowledged. The length field specifies the number of characters carried in the data field. It should be in the range of 0 to 500. For ACK packets, length should be set to zero.

Sender Program (sender)

You should implement a sender program, named sender. Its command line input includes the following: <host address of the network emulator>, <UDP port number used by the emulator to receive data from the sender>, <UDP port number used by the sender to receive ACKs from the emulator>, <timeout interval>, and <name of the file to be transferred> in the given order.

Upon execution, the sender program should be able to read data from the specified file and send it using the Go-Back-N protocol to the receiver via the network emulator. <u>The initial window size should be set to N=10 packets</u>. After all contents of the file have been transmitted successfully to the receiver (and corresponding ACKs have been received), the sender should send an EOT packet to the receiver. The EOT packet is in the same format as a regular data packet, except that its *type* field is set to 2 and its *length* is set to zero. The sender can close its connection and exit only after it has received ACKs for all data packets it has sent and received an EOT from the receiver. To keep the project simple, <u>you can assume that the end-of-transmission packet never gets lost in the network</u>.

In order to ensure reliable transmission and congestion control, your program should implement the **congestion-controlled Go-Back-N** protocol as follows:

If the sender has a packet to send, it first checks to see if the window is full, that is, whether there are N outstanding, unacknowledged packets. If the window is not full, the packet is sent, the appropriate variables are updated, and a timer is started if not done before. The sender will use only a single timer that will be set for the oldest transmitted-but-not-yet-acknowledged packet. If the window is full, the sender will try sending the packet later. When the sender receives an acknowledgement packet with seqnum n, the ACK will be taken to be a cumulative acknowledgement, indicating that all packets with a sequence number up to and including n have been correctly received at the receiver. If a timeout occurs, the sender sets N=1 retransmits the packet that caused the timer to timeout (one packet and not all the non-ACKed packets). If an ACK is received but there are still additional transmitted-but-yet-to-be-acknowledged packets, the timer is restarted. If there are no outstanding packets, the timer is stopped. If the ACK is a new ACK (and not a duplicate ACK), N is incremented by 1 up to a maximum of 10 (N cannot exceed 10).

Output

For both testing and grading purposes, your *sender* program should be able to *generate three log files*, named as *seqnum.log*, *ack.log*, *N.log*. Whenever a packet is sent, its sequence number should be recorded in *seqnum.log*. The file *ack.log* should record the sequence numbers of all the ACK packets that the sender receives during the entire period of transmission. *N.log* should record every time the value of N is changed. *The format for these log files is one timestamp, space, and one number per line* (e.g. in *seqnum.log* t=0 0 for packet #0 sent at t=0). The timestamp is a number that is incremented by one at every new event (a new packet to be sent, receiving an ACK, or timeout). Be careful, some actions are executed at the same timestamp, e.g. if a timeout occurs at t=T, there should be an entry t=T in

seqnum.log for the retransmission as well as in N.log for (re)setting N to 1. You must follow this format to avoid losing marks.

Receiver Program (receiver)

You should implement the receiver program, named as receiver, on a UNIX system. Its command line input includes the following: <nostname for the network emulator>, <UDP port number used by the link emulator to receive ACKs from the receiver>, <UDP port number used by the receiver to receive data from the emulator>, and <name of the file into which the received data is written> in the given order.

When receiving packets sent by the sender via the network emulator, it should execute the following:

- check the sequence number of the packet;
- if the sequence number is the one that it is expecting, it should send an ACK packet back to the sender with the sequence number equal to the sequence number of the received packet;
- in all other cases, it should discard the received packet and resend an ACK packet for the most recently received in-order packet;

After the receiver has received all data packets and an EOT from the sender, it should send an EOT packet then exit.

Output

The receiver program is also required to generate a log file, named as <u>arrival.log</u>. The file <u>arrival.log</u> should record the sequence numbers of all the data packets that the receiver receives during the entire period of transmission. <u>The format for the log file is one number per line. You must follow the format to avoid losing marks.</u>

Network Emulator (nEmulator)

When the link emulator receives a data packet from the sender, it will discard it with the specified probability. Otherwise, it stores the packet in its buffer, and later forwards the packet to the receiver with a random amount of delay (less than the specified maximum delay). The same behaviour applies to ACKs received from the receiver. EOT packet from the sender is never discarded. It is forwarded to the receiver once there are no more data packets in the buffer. EOT packet from the receiver is never discarded. It is forwarded to the sender once there are no more ACKs in the buffer.

To run nEmulator, you need to supply the following command line parameters in the given order:

- <emulator's receiving UDP port number in the forward (sender) direction>,
- <receiver's network address>,
- <receiver's receiving UDP port number>,
- <emulator's receiving UDP port number in the backward (receiver) direction>,
- <sender's network address>,

- <sender's receiving UDP port number>,
- <maximum delay of the link in units of millisecond>,
- <packet discard probability>,
- <verbose-mode> (Boolean: Set to 1, the network emulator will output its internal processing, one
 per line, e.g. receiving Packet seqnum /ACK seqnum, discarding Packet seqnum /ACK seqnum,
 forwarding Packet seqnum /ACK seqnum).

Hints

- Further description of the GBN sender and receiver can be found in Chapter 3 slides and your textbook (check the FSM of the sender and the receiver) but again here we are implementing GBN with a twist!
- You must run the programs in the CS Undergrad Environment
- Experiment with network delay values and sender time-out to understand the performance of the protocol.
- Run nEmulator, receiver, and sender on three different machines <u>in this order</u> to obtain meaningful results.

Example Execution

- 1. On the host host1: nEmulator 9991 host2 9994 9993 host3 9992 1 0.2 0
- 2. On the host host2: receiver host1 9993 9994 <output File> 3. On the host host3: sender host1 9991 9992 50 <input file>

Procedures

Due Date

The assignment is due on Monday, March 22nd, 2021, at midnight (11:59 PM).

Late submission policy: 10% penalty every late day, up to 3 late days. Submissions not accepted beyond 3 late days.

Hand in Instructions

Submit all your files in a single compressed file (.zip, .tar etc.) using LEARN.

You must hand in the following files / documents:

- Source code files.
- Makefile (if applicable): your code **must** compile and link cleanly by typing "make" or "gmake".
- README file: this file must contain instructions on how to run your program, which undergrad
 machines your program was built and tested on, and what version of make and compilers you
 are using.

Your implementation will be tested on the machines available in the **undergrad environment**.

Documentation

Since there is no external documentation required for this assignment, you are expected to have a reasonable amount of internal code documentation (to help the markers read your code).

You will lose marks if your code is unreadable, sloppy, and inefficient.
